## 2024\_28\_III\_OOPS Using Java Lab

### REC\_2028\_OOPS using Java\_Week 7\_CY

Attempt : 1  
Total Mark : 40  
Marks Obtained : 40

#### Section 1 : Coding

##### 1. Problem Statement

Jeevan is developing a fitness-tracking application to monitor daily physical activity.

The application incorporates a FitnessTracker class that implements two interfaces: StepCounter for tracking the number of steps taken and CalorieCalculator for estimating total calories burned based on total steps.

Jeevan needs your help creating a program.

##### Note

The calorie calculation formula is:  $\text{Total caloriesBurned} = (\text{total steps} / 100.0) * 20.0$ .

### ***Input Format***

The first line of input is an integer  $n$ , representing the number of days Jeevan wants to input data.

The second line consists of space-separated integers, representing the number of steps Jeevan took on each day.

### ***Output Format***

The first line of output prints: "Total Steps: <totalSteps>", where '<totalSteps>' is the sum of steps (integer) taken over ' $n$ ' days.

The second line prints: "Calories Burned: <caloriesBurned>", where '<caloriesBurned>' is the estimated total calories (double-point number) burned based on the total steps taken rounded off to two decimal places.

Refer to the sample output for the formatting specifications.

### ***Sample Test Case***

Input: 3

340 234 987

Output: Total Steps: 1561

Calories Burned: 312.20

### ***Answer***

```
import java.util.Scanner;
```

```
// You are using Java
```

```
interface StepCounter {  
    void countSteps(int steps);  
    int getTotalSteps();  
}
```

```
interface CalorieCalculator {  
    double calculateCaloriesBurned(int totalSteps);  
}
```

```
class FitnessTracker implements StepCounter, CalorieCalculator {  
    private int totalSteps;
```

```

public FitnessTracker() {
    this.totalSteps = 0;
}

public void countSteps(int steps) {
    this.totalSteps += steps;
}

public int getTotalSteps() {
    return this.totalSteps;
}

public double calculateCaloriesBurned(int totalSteps) {
    return (totalSteps / 100.0) * 20.0;
}
}

class Main
{

    public static void main(String[] args) {
        Scanner scanner = new Scanner(System.in);

        FitnessTracker tracker = new FitnessTracker();

        int n = scanner.nextInt();

        for (int i = 0; i < n; i++) {
            int steps = scanner.nextInt();
            tracker.countSteps(steps);
        }

        int totalSteps = tracker.getTotalSteps();
        System.out.println("Total Steps: " + totalSteps);

        double caloriesBurned = tracker.calculateCaloriesBurned(totalSteps);
        System.out.printf("Calories Burned: %.2f%n", caloriesBurned);

        scanner.close();
    }
}

```

**Status :** Correct

**Marks :** 10/10

## 2. Problem Statement

Alex and Bob are designing a control system for household appliances, and one of the appliances is a washing machine. You want to create a program to help them that models the washing machine as a motor and calculates its electricity consumption based on its capacity.

Define an interface named `Motor` with the following methods:

```
void run() double consume(double capacity)
```

Create a class called `WashingMachine` that implements the `Motor` interface.

In the `WashingMachine` class:

Implement the `run()` method to print "Washing machine is running." Implement a `consume()` method to print "Washing machine is consuming electricity." Implement the `consume(double capacity)` method to calculate the electricity consumption (in kWh) of the washing machine based on its capacity. The formula for electricity consumption is  $(\text{capacity} * 0.05)$ .

### ***Input Format***

The input consists of a double value representing the capacity of the washing machine in kW.

### ***Output Format***

The first line of output prints "Washing machine is running."

The second line prints "Washing machine is consuming electricity."

The third line prints "Electricity consumption: X kWh" where X is a double value, rounded off to two decimal places, representing the electricity consumption.

Refer to the sample output for formatting specifications.

### ***Sample Test Case***

Input: 2.5

Output: Washing machine is running.  
Washing machine is consuming electricity.  
Electricity consumption: 0.13 kWh

**Answer**

```
import java.util.Scanner;

interface Motor {
    void run();
    void consume();
    double consume(double capacity);
}

class WashingMachine implements Motor {
    public void run() {
        System.out.println("Washing machine is running.");
    }

    public void consume() {
        System.out.println("Washing machine is consuming electricity.");
    }

    public double consume(double capacity) {
        return capacity * 0.05;
    }
}

public class Main {
    public static void main(String[] args) {
        Scanner scanner = new Scanner(System.in);

        WashingMachine washingMachine = new WashingMachine();

        double capacity = scanner.nextDouble();

        washingMachine.run();
        washingMachine.consume();

        double consumption = washingMachine.consume(capacity);
        System.out.printf("Electricity consumption: %.2f kWh", consumption);

        scanner.close();
    }
}
```

**Status : Correct**

**Marks : 10/10**

### 3. Problem Statement

Maria, an online store owner, is looking to implement a pricing system that calculates the final price of products after applying discounts. She needs a program that takes the original price of a product and the discount percentage as input and computes the final discounted price. The discount is applied as a percentage of the original price. Maria wants to ensure that the final price is formatted to display exactly two decimal places.

Implement this functionality using the PriceCalculator interface and the DiscountCalculator class.

#### ***Input Format***

The first line of input consists of the original price (a double value).

The second line of input consists of a discount percentage (a double value).

#### ***Output Format***

The output displays the final price after the discount, adhering to the following format: "Final Price after discount: \$[final\_price]".

Here, [final\_price] should be replaced with the calculated final price, formatted as a currency value with two decimal places.

Refer to the sample output for the formatting specifications.

#### ***Sample Test Case***

Input: 100.0

10.0

Output: Final Price after discount: \$90.00

#### ***Answer***

```

import java.util.Scanner;

interface PriceCalculator {
    double calculatePrice(double originalPrice, double discount);
}

class DiscountCalculator implements PriceCalculator {
    public double calculatePrice(double originalPrice, double discount) {
        return originalPrice - (originalPrice * discount / 100);
    }
}

class Main {
    public static void main(String[] args) {
        Scanner scanner = new Scanner(System.in);
        double originalPrice = scanner.nextDouble();
        double discount = scanner.nextDouble();
        PriceCalculator calculator = new DiscountCalculator();
        double finalPrice = calculator.calculatePrice(originalPrice, discount);
        System.out.printf("Final Price after discount: $%.2f\n", finalPrice); //
        Formats output to 2 decimal places
    }
}

```

**Status :** Correct

**Marks :** 10/10

#### 4. Problem Statement:

Ray is developing a tax calculation program in Java. The program includes an interface named TaxCalculator with a method to calculate tax based on salary. The SimpleTaxCalculator class implements this interface and determines the tax to be paid based on the salary amount using progressive tax slabs.

Your task is to implement this system. The program first takes an integer T representing the number of test cases, followed by T salary values. For each salary, calculate the total tax to be paid based on the following progressive tax rules:

For the first 50,000 of salary, the tax rate is 5%. For the next 50,000 (i.e., from 50,001 to 1,00,000), the tax rate is 10%. For any amount above

1,00,000, the tax rate is 20%. (That is, only the amount above 1,00,000 is taxed at 20%.)

### Example

Input

3

78000

110000

23000

Output

5300

9500

1150

### Explanation

For Salary Rs. 78,000

$$\text{Tax} = 0.1 * (78,000 - 50,000) + 0.05 * 50,000 = 5,300$$

For Salary Rs. 1,10,000

$$\text{Tax} = 0.2 * (110000 - 100000) + 0.1 * 50,000 + 0.05 * 50,000 = 9,500$$

For Salary Rs. 23,000

$$\text{Tax} = 0.05 * 23,000 = 1,150$$

### ***Input Format***

The first line of the input consists of an integer, T, representing the number of test cases.

The next T lines of the input consist of a single integer, representing the annual salary of an individual, separated by a line.

### ***Output Format***

The output displays the calculated tax as an integer for each test case,

separated by a line.

Refer to the sample output for the formatting specifications.

### **Sample Test Case**

Input: 2

100

300

Output: 5

15

### **Answer**

```
import java.util.Scanner;
```

```
interface TaxCalculator {  
    int calculateTax(int salary);  
}
```

```
class SimpleTaxCalculator implements TaxCalculator {  
    public int calculateTax(int salary) {  
        int tax = 0;
```

```
        if (salary <= 50000) {  
            // First slab: 0 to 50,000 at 5%  
            tax = (int)(salary * 0.05);  
        } else if (salary <= 100000) {  
            // First 50,000 at 5% + remaining at 10%  
            tax = (int)(50000 * 0.05 + (salary - 50000) * 0.10);  
        } else {  
            // First 50,000 at 5% + next 50,000 at 10% + remaining at 20%  
            tax = (int)(50000 * 0.05 + 50000 * 0.10 + (salary - 100000) * 0.20);  
        }  
    }
```

```
        return tax;  
    }  
}
```

```
class Main {  
    public static void main(String[] args) {  
        Scanner scanner = new Scanner(System.in);
```

```
int T = scanner.nextInt();

TaxCalculator taxCalculator = new SimpleTaxCalculator();

for (int i = 0; i < T; i++) {
    int salary = scanner.nextInt();
    int tax = taxCalculator.calculateTax(salary);
    System.out.println(tax);
}

scanner.close();
}
```
